 2019.7.4

# Principles of BOLD fMRI

# fMRI BOLD signal

- fMRI does not measure neuronal activation directly, but the consequences of metabolic processes associated with activation.
- Blood Oxygenation Level Dependent (BOLD)** contrast  
*(Ogawa et al., PNAS, 1990; Turner et al., MRM, 1991)*
- The MR signal in the vicinity of blood vessels and in perfused brain tissue decreased with a decrease in blood oxygenation.

# Membrane Potential

- Neuronal membranes prevent free diffusion of ions.
- A neuron at rest has...
  - a greater concentration of  $K^+$  inside its membrane;
  - a greater concentration of  $Na^+$ ,  $Ca^{2+}$ , and  $Cl^-$  outside.
- The difference in electric potential between the interior and the exterior of a biological cell is typically ranged from  $-40$  mV to  $-80$  mV.

## Action Potential

- **All-or-none** principle
  - Action potentials are said to be all-or-none signals, since either they occur fully or they do not occur at all.
- **Depolarization**
  - At the beginning of the action potential, the **Na<sup>+</sup> channels** open and Na<sup>+</sup> moves into the axon, causing depolarization.
- **Repolarization (Sodium-potassium pumps)**
  - Repolarization occurs when the **K<sup>+</sup> channels** open and K<sup>+</sup> moves out of the axon. This creates a change in polarity between the outside of the cell and the inside.

The resting potential is around -70 millivolts (mV) and the threshold potential is around -55 mV.

## Synapses

- **Glutamate:** One of the most important excitatory neurotransmitters.
- **excitatory postsynaptic potential (EPSP):** A depolarization of the postsynaptic cell membrane.
- **γ-aminobutyric acid (GABA):** One of the most important inhibitory neurotransmitters.
- **inhibitory postsynaptic potential (IPSP):** A hyperpolarization of the postsynaptic cell membrane.

## Neurovascular Coupling

- ATP is essential for neural activity
  - Restoration of ionic gradients
  - neurotransmitter recycling
- Glycolysis
  - a small amount of ATP (2 ATP) → produce lactate
- **Oxidative glucose metabolism (90% in brain)**
  - a large amount of ATP (34 ATP)
- Cerebral metabolism depends on a constant supply glucose and oxygen

## Neurovascular Coupling

- Multiple mechanisms...
  - Astrocytes links neurotransmitter activity (glutamate cycling) to vascular responses.
  - Direct neuronal innervation of smooth muscle cells can also control blood flow.
- Requirement of metabolic nutrients
- Elimination of waste products
  - CO<sub>2</sub> and excessive heat

## Neurovascular Coupling

- A continuous supply of energy substrates is maintained by CBF
- Neural activity
  - Blood perfusion via capillaries ↑
  - regional cerebral blood flow (rCBF) ↑
  - regional cerebral blood oxygenation (rCBO) ↑
- Changes in rCBF or rCBO can be used to map brain activity
  - Functional neuroimaging

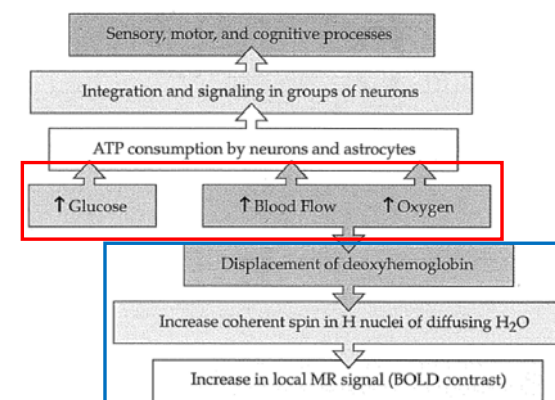

Brain vascular system: glucose and oxygen

Zlokovic & Apuzzo, 1998.

## Biomarkers of brain activation

- Oxygen
  - **BOLD fMRI**
  - Functional near-infrared spectroscopy (fNIRS)
  - Positron emission tomography (PET)
- Blood Flow
  - Arterial spin labeling (ASL)
- Glucose (still impractical now)
  - PET
  - MR CEST techniques

## CBF and O<sub>2</sub> Consumption Mismatch

- During neural activity...
  - The fractional increases in CBF and glucose consumption are similar in magnitude.
  - Oxygen consumption increases much less than CBF.
- → A net increase of oxygen in the blood and tissue.

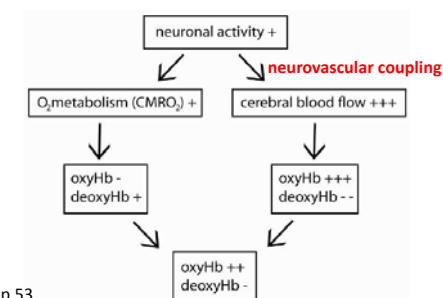

**CMRO2: cerebral metabolic rate of oxygen**

Ances et al., JCBFM 2001.

## Metabolic and hemodynamic changes

- Mismatch between CBF and O<sub>2</sub> consumption
- Neural/Brain activation
  - Elevated oxy-Hb fraction
  - Decrease deoxy-Hb fraction

Neuroimaging – Methods, pp.53.

# Hemoglobin

## Oxygenated Hemoglobin

- Diamagnetic
- Doesn't distort surrounding magnetic field
- No signal loss in BOLD signal

## Deoxygenated Hemoglobin

- Paramagnetic
- **Distorts surrounding magnetic field**
- **Signal loss in BOLD signal !!!**

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>

# fMRI BOLD signal

- $t = 0s$ , a steady state in which there is an given amount of oxygenated and deoxygenated hemoglobin.
- $t = 1s$ , an increased of deoxygenated hemoglobin due to the oxygen demands of neuronal activation.
- $t = 6s$ , an increased of blood supply and oxygenated hemoglobin "flush away" the deoxygenated ones.

Matthijs Vink, Preprocessing and analysis of functional MRI data, 2007.

# Neuronal activity and BOLD

- Blood-oxygenation level dependent (BOLD)
- BOLD fMRI detects the alterations in
  - The level of deoxygenated hemoglobin
  - Cerebral blood volume

Mandeville et al., MRM 1999.

# Common fMRI protocol

- Single-Shot 2D EPI (GRE-EPI), T2\* weighting
  - Repetition Time = 2000 ms
  - Echo Time = 20 ms
  - Flip Angle = 70~90°
  - NEX = 1
  - Slice thickness = 3.4 mm
  - Field of View = 220 x 220 mm<sup>2</sup>
  - Matrix size = 64 x 64
  - Volume number = 240 ~ 360
- (depends on experiment design)

1 voxel ~ 10<sup>6</sup> neurons

3.44 x 3.44 x 3.40 mm<sup>3</sup>

## EPI BOLD raw images

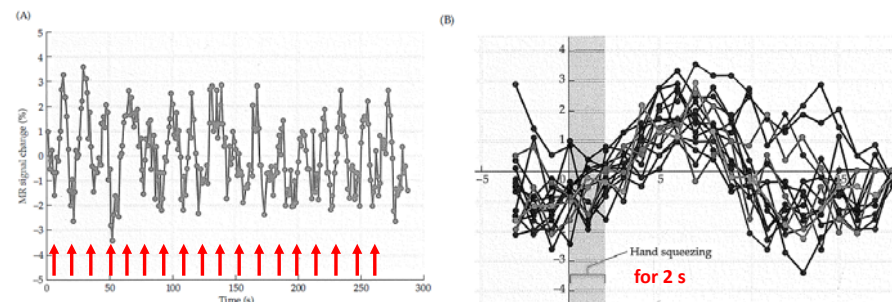

Chia-Feng Lu

<http://practicalfMRI.blogspot.tw/2012/05/rare-intermittent-epi-artifacts-spiking.html>  
<http://www.ym.edu.tw/~cflu>

17

## fMRI signal example

- A sample fMRI time course from a single voxel in the motor cortex during a task in which the subject squeezed her hand for 2 s every 16 to 18 s.

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

18

## Neurovascular Coupling Properties

- Use of vascular responses to infer neural activity
  - **Time**: lack of temporal information in vascular response
  - **Space**: focal activation of neurons  $\leftrightarrow$  local vascular response?
  - **Amplitude**: linear relationship?

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

19

## Alteration Factors

- Disease
  - the chemical mediators
  - the dynamics of the vascular system
  - hypertension, diabetes, and AD alter ionic channels on vascular smooth muscle
- Aging
  - change the vascular system
  - increasing tortuosity or reducing elasticity of the blood vessels
- Pharmacology
  - Diazoxide is used as a vasodilator  $\rightarrow$  large vascular responses with little or no change in neural activity.
  - Hypercapnia (the concentration of  $\text{CO}_2$  in the blood  $\uparrow$ )  $\rightarrow$  vasodilation.

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

20

## Experimental Design of fMRI

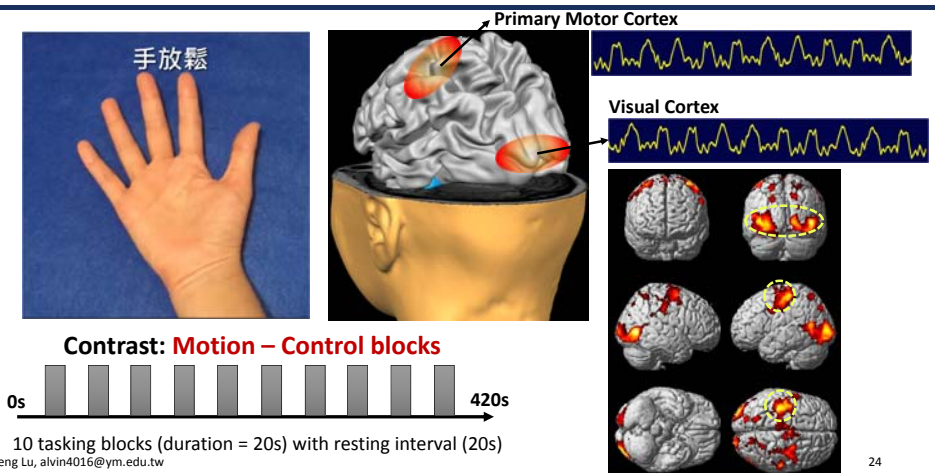

## Goal of Experimental Design

- To manipulate the participants experience and behavior in some way that is likely to produce a functionally specific neurovascular response.
- What can we manipulate?
  - **Stimulus properties** (what is presented?)
  - **Stimulus timing** (when is it presented?)
  - **Participant instructions** (what do subjects do with it?)

## Types of Experimental Design

- **Simple Subtraction**
- **Categorical Design**
  - Cognitive subtraction: the assumption of pure insertion
- **Factorial Design**
  - Considering the interaction between multiple factors
- **Parametric Design**
  - Correlating behavior with brain activity

## Simple Subtraction

## Categorical Design (1/3)

Comparing the brain activity between stimulus types.

Example:

- **Stimulus:** visual presentation of 12 common nouns.
- **Tasks:** decide for each noun whether it refers to an **animate** or **inanimate** object.

## Categorical Design (2/3)

- **Cognitive subtraction:** the assumption of **pure insertion**

**Aim**

- Neural structures underlying a single process Y (e.g. face recognition)?

**Procedure**

- Contrast: [Task with Y] – [control task without Y] = Y

## Categorical Design (3/3)

To identify the face recognition area...

**Which one is the proper Control stimulus?**

Target Face

Scrambled

A Bottle

Male Face

## Factorial Design (1/2)

- Combining two or more factors within a task and looking at the effect of one factor on the response to other factor.

• **Main effects**

- Main effect of task:  
 $(A1+B1) - (A2+B2)$
- Main effect of stimuli:  
 $(A1+A2) - (B1+B2)$

Stimuli (A/B)

Color Gray-level

**Task (1/2)**

Viewing Naming

A1	A2
B1	B2

## Factorial Design (2/2)

- Combining two or more factors within a task and looking at the effect of one factor on the response to other factor.

- Interaction of task and stimuli**

- (A1 – B1) – (A2 – B2)

Does not make the assumption of pure insertion.

Stimuli (A/B)

Color Gray-level

		Task (1/2)	
		Viewing	Naming
Color	Gray-level	A1	A2
	Color	B1	B2

## Parametric Design

Exploring systematic changes in brain responses according to some performance attributes of the task.

Parametric designs use **continuous rather than categorical design**.

For example, we could **correlate response times with brain activity**.

## Stimulus Delivery

- MRI compatible hardware**

- In-room viewing monitor/projector
- Goggles with integrated EyeTracking cameras
- Audio system
- Response pads/grips/buttons
- Trigger/synchronization box (MR scanner ↔ stimulus presentation software)

- Stimulus presentation software**

- E-prime (BIOPAC Systems)
- Presentation (Neurobehavioral Systems)

## Stimulus Timing Design

- Block design**

- Combine BOLD response to a number of continuous trials (events)

- Event-related (ER) design**

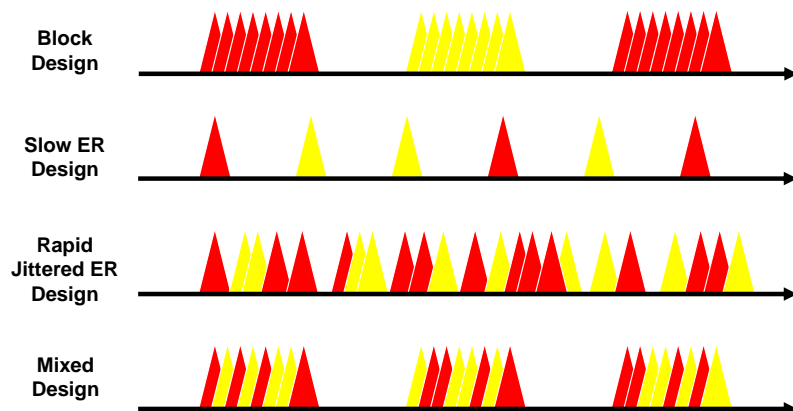

- Obtain the BOLD response to a single event

- The more *efficient* a design, the less scan time is needed to achieve sufficient *power*.

## Design Types

▲ = trial of one type    ▲ = trial of another

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>  
<http://www.ym.edu.tw/~cflu>

33

Chia-Feng Lu

## Block Design

- A design in which the task is presented in so-called blocks (15~30s), alternated with resting blocks.
- The number of scans should be equal in all conditions, so that the variance in all factors is the same.
- The longer the blocks are, the more chance there is for a correlation with low-frequency noise.
- The strength of the brain signal can decrease over time.

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

34

## Block Design

- **Box-car function**
  - A 0 for no-task and a 1 for task period
- **Hemodynamic (BOLD) changes do not suddenly activate and stop activating in the way modeled by the box-car function.**
  - A better estimation by convolving the box-car input function with an **HRF**.

Matthijs Vink, Preprocessing and analysis of functional MRI data, 2007.

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

35

## BOLD and HRF characteristics

- The relationship between neural activation and BOLD signal
  - Neuronal firing and postsynaptic potentials occur very soon (tens to hundreds of milliseconds)
  - BOLD: initial dip (~1s) → maximal value (4~6s) → return to baseline (~20s)
- **Hemodynamic response function (HRF)**

**BOLD impulse response**

Friston et al, Neuroimage, 1995, 1998.

Chia-Feng Lu

<http://www.ym.edu.tw/~cflu>

36

## Pros of Block Designs

- high detection power of activated voxel/region
- has been the most widely used approach for fMRI studies
- accurate estimation of hemodynamic response function is not as critical as with event-related designs

## Cons of Block Designs

- poor estimation power to differentiate the time courses in response to different conditions
- very predictable for subject
- Can't look at effects of single events
- becomes unmanageable with too many conditions (e.g., more than 4 conditions + baseline)

## Slow Event-Related (ER) designs

## Pros of Slow ER Designs

- excellent estimation of BOLD changes
- useful for studies with delay periods
- very useful for designs with motion artifacts because you can tease out artifacts

## Cons of Slow ER Designs

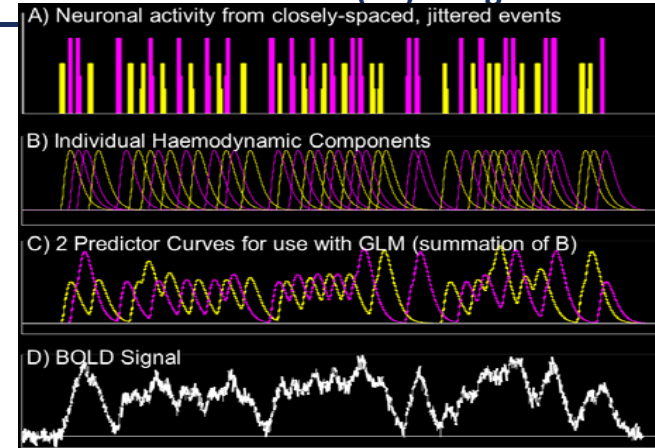

- poor detection power because of very few trials per condition
- subjects can get VERY bored and sleepy with long ITI.

How about making it fast?

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>  
<http://www.ym.edu.tw/~cflu>

## Rapid Jittered Event-Related (ER) designs

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>  
<http://www.ym.edu.tw/~cflu>

## Why jitter?

- Yields larger **fluctuations** in signal

When pink is on, yellow is off  
 → pink and yellow are anticorrelated

Includes cases when both pink and yellow are off  
 → less anticorrelation

- Without jittering predictors from different trial types are strongly **anticorrelated**.
  - As we know, the GLM doesn't do so well when predictors are correlated (or anticorrelated)

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>  
<http://www.ym.edu.tw/~cflu>

## Pros of Rapid-ER Designs

- High detection power compared to slow ER design
- Trials can be put in unpredictable order.
- Subjects don't get so bored.

fMRI slides from <http://culhamlab.ssc.uwo.ca/fmri4newbies/Tutorials.html>  
<http://www.ym.edu.tw/~cflu>

## Summary of Experiment Design

- **Rules of thumb**

- **Blocked Designs:**

- Powerful for detecting activation
    - Useful for examining state changes

- **Event-Related Designs:**

- Powerful for estimating time course of activity
    - Allows determination of baseline activity
    - Best for post hoc trial sorting

- **Mixed Designs**

- Best combination of detection and estimation
    - Much more complicated analyses

Quoted from Yingying's slide.
